RESULTS: The results of this work indicate that the incidence of pedicle fractures or loosening during deformation correction potentially could be reduced if vertical links were used to distribute forces applied to the pedicles. This idea may be extended to the design of rod constructs in which incremental distraction is performed. Further studies in this area are underway.

ACKNOWLEDGEMENTS: The authors gratefully acknowledge partial funding of this work by EBI, L.P., and the cooperation of Pacific Research in molding vertebral. The authors also wish to thank Alan Burke of EBI, Peter Czuwala and Stephanie Spomer for their technical assistance.
